## Bamboo shrimp care sheet

Bamboo shrimp (*ayosis moluensis*) has a lot of different names. However, this is the same type of name as one of all the shrimps. Their feeding method is their specificity. In this article we will tell you all the intricate details about the types of shrimp, how to keep them in the tank and why they are called so. The habitat of wild ayosis moluensis comes from the Indo Pacific region and Malaysia. They live in large herds in slow rivers and streams, feeding on various microorganisms, small particles of food. Shrimps have a quiet and peaceful nature, allowing them to settle in community tanks with small fish and large fish. Appearance you should keep in mind that the commercial appeal of the species can take on the appearance of a variety of new species of bamboo shrimp. Often one of the same types is sold under a different name. Accordingly, these shrimps can vary greatly because they do not yet have a classification. In this article, you will find a general description of the species and the fact that for all breeds, how to store it in a tank. The adult size is about 4 inches (10 cm). Its lifespan is about 2-3 years or a little longer provided by good conditions of life. Perhaps, this happens because of the stress experienced during transport as well as new tank conditions where they get exposed. Coloring can be brown, red, sandy green or yellow. It depends on many factors: the place where the shrimp was caught, the speciality of the diet, the process of shedding, the dominant tank plants in the tank factory, etc. That is why it is almost impossible to predict what color the shrimp will get from the new tank. The prawns have white or bright yellow strips along the back. A feature of this type of shrimp is a web-like pan with the first two pairs of legs. There is a kind of hook in the pan so that the shrimp can filter the food from the water. The shrimp is rather large and prevents it from being transferred to the water flow. Bamboo shrimp use fan-shaped legs to hang water and capture microbes, plant debris, algae and other small litter. In general, bamboo shrimp stay in places with strong water flow, climbing fan-like legs and water. If you look closely, you can see how to close the pan, lick it, and then open it again. Tank science name *Ayosis Spderaim*Bamboo Shrimp, Tree Shrimp, Flower Shrimp, Mountain Shrimp, Singapore Flower Shrimp, Tank Size 10 Gallons (40L) and More Temperance Peace Omnivoruo Temperature 75-81 F (24-28°C)pH7-7.5 sizes up to 2 inches (5 cm) are permitted. Tank water should be neutral or slightly alkaline (pH value is about 7 or more). As for tank water hardness, it should not be less than 6-80 GH. You can store these prawns in soft or slightly acidic water. The tank needs width, Plenty of water flow. As for ammonia and nitrites - they should not be present in shrimp and tanks. Besides, it is recommended to keep nitrate levels as low as possible - in some cases it should not exceed 40-50 mg/l. The tank water temperature should be within 75-81 F (24-28 °C). When the temperature is lowered to 22 °C, they obviously do not feel well. They look very unusual in community tanks. They can sit at a few heights and catch the flow of water with the fans. Taking into account the speciality of feeding and behavior, we can conclude that good filtration and clean water are mandatory requirements for keeping shrimp in the tank. You can use both internal and external filters, the important thing is that they provide the necessary water flow strength. It is recommended to put stones, hangs, large tank plants along the water flow. Bamboo prawns will sit on them like monuments and catch flowing food. It's important not to starve shrimp, which can easily happen given the unusual feeding methods. The first sign that shrimp are starving is that they spend more time at the bottom of the tank and start looking for food. Because, in general, they usually sit in some high place in the tank and catch food from the water flow. It's not a small shrimp, but it can hide so well that it's hard to find even in an empty tank. If you are not afraid of shrimp, they shake on tank plants or walk along the bottom of the tank in search of food. I can't imagine how I enjoy the moment of cleaning the bottom of the feeding tank, dig out tank plants or feeding the fish with small grain foods like frozen brine shrimp. They try to get closer to the center of such an event. It is also activated when washing the tank filter, and small dust and food fall off the filter and are carried into the flow. With that in mind, prawns are starving in pet stores! So when they enter the new tank, they walk along the floor and start looking for food. This is a very common behavior for shrimp purchased from pet stores. Therefore, be prepared to supply them high in the first place. Shrimp should be fed as a high-quality dry food for premature fish. Very small grains for fish youth, pellets that slowly down are especially good. Encapsulated eggs of frozen daphnia and cyclop, live brine shrimp naefei and brine prawns will also do. Food driven to the bottom of the tank is easily swept away by shrimp. Sometimes it happens that there is no stopped food in the tank and it won't be for a few periods of time, but the shrimp tank refuses to go round the bottom and find food there. They just sit near the pump and filter the water flow (which is missing) and they can even die this way. In this case, the pump must be released before feeding. When the flow of the tank disappears, the shrimp understands that the food will not come to them, Bottom. Compatible and tank mate bamboo shrimp has very easy properties and can live in groups. However, they tend to show territorial dependence on small tanks, even without hurting each other. The main thing for them in this case is to push the other shrimp from the high place to get there. Tank mates should be peaceful and small. Considering the other prawns, you can take cherry and amano prawns. The same advice is about fish if you choose to be a tank mate. You should avoid most of the puffer fish, cichlids. Bamboo prawns are completely helpless and harmless. How do shrimp grow? They often shed their own squares immediately after they grew, shed, when the new Chitinath uppers were sweaty. We must mention that the shedding process is a serious challenge. However, if the tank conditions are favorable, the process ends successfully. Let me remind you that all crustaceans sometimes shed spiritedly. They take off the old Chitinath uppers, which become smaller. They literally shed their skin, which is not easy at all. But they can still do it every time. Also, during shedding they grow new parts of the body, instead of the ones they lost. All the prawns were taken away from the warm country to us, and they went through hard times during the traffic and live in different tanks before arriving here. So, create comfortable tank conditions for these shrimp and in a few months all the missing parts of the body will grow back. Sex you can see between women and men, because women have larger abdomens and longer pleurals. Men are slim. Males have the first pair with different limbs - they are more developed and have small claws that they use during mating. Breeding is very complex. The bamboo shrimp development cycle is rather complex and clearly indicates to the estuarine or sea habitat of their ancestors. The female attaches hundreds of small eggs (about 1.8 mm in diameter) to the pleurals and carries them for about 22 days. Small larvae that can swim hatches from these eggs. But they soon die while shedding or entering the tank filter, or if they do not throw them away in a timely manner, they are eaten by their parents. The problem is that adolescents can grow successfully only in seawater or desolate water (about 28 grams per liter of salt per liter of water) and require a specialized diet: first vegetables and then zooplankton. Quickly descend the river flow from the wild larvae and enter the water to reach the downstream of the river. It is possible but difficult to grow larvae in the home. Without exaggeration, regularly supplying larvae and maintaining almost ideal hydrogenation conditions in the tank would be quite a feat. Sergei is Meethepet.com founder and author of the book. He loved aquarium animal life from an early age. His favorite aquarium Biotops (Amazon River) with Echinodorus and Angelfish. However, for many years he had the experience of keeping almost all kinds of freshwater fish and shrimp. Shrimp.
